THE LAST FORECAST

Why no one can tell you
what AI will do to your job
and what we can still decide

2026 – 2046

E.L. DE VITO

The Last Forecast

Why no one can tell you what AI will do to your job and what we can still decide

by E.L. De Vito

This book was developed with the support of Claude, ChatGPT and Grok; parts of the text and of the code were written with the help of artificial intelligence.

Introduction

They will tell you it has happened before.

That every time a machine took a person's place, someone announced the end of work, and work came back. Mechanical looms, tractors, computers: each time the fear, each time the recovery.

In the long run, that is true. But the people who tell you so usually forget two things.

The first is how long the long run lasted. In England in the first decades of the nineteenth century, output per worker grew year after year while real wages stood still. For thirty years. An entire generation worked inside the Industrial Revolution without seeing its fruits. Work did come back, yes: to their children, in other cities, in other trades. Not always to the people who had lost it.

The second thing matters even more. Each time there was somewhere to go. Those who left the fields found the factory. Those who left the factory found the office, the counter, the service desk. Work done with the head was the refuge: the part that machines could not do.

This time the machine walks straight into that refuge. It reads, writes, classifies, answers, checks. And together with robots it is beginning to approach manual work as well. If both refuges close, where do people go?

The signals are already here, and they are not encouraging.

The first concerns the wheel that has saved us so far: the birth of new tasks that only people can perform. Daron Acemoglu and Pascual Restrepo measured it in the United States. Until 1987, for every task machines took away from people, almost one new task appeared. After 1987, about half of one. The wheel still turns, but at half speed. And that was before artificial intelligence.

The second concerns those entering the world of work. In the United States, from late 2022 to the summer of 2026, the number of 22- to 25-year-olds employed in the occupations most exposed to AI fell by almost 13 percent, while their peers in less exposed jobs grew by 8 percent. In the last year the decline is 4.4 percent, more than twice that of their less exposed peers, and it is starting to reach those aged 26 to 30. Nobody fired them. They simply were not hired.

The third concerns who gets paid. For twenty years, all over the world, the share of the wealth produced that goes to those who work has been shrinking. This too began before AI. AI pushes in the same direction.

This book argues a thesis, and states it right away. Over the next twenty years artificial intelligence will make economies richer and, at the same time, reduce job opportunities across a large part of economic activity. New jobs will come, but not enough of them, not soon enough and not for the same people. The young will pay first, as the entrance door narrows without a sound. And unless the rules change, the value produced by machines will go mostly to those who own them.

To put this thesis to the test, a model of the world economy was built: three large regions, households divided by income, firms, a state that collects and spends. Four thousand possible futures, each calculated twice, with the new wave of AI and without it, starting from the same conditions. It is the most honest way there is to isolate the effect of the technology from everything else.

And here is what makes the result hard to ignore. The model was built on cautious assumptions, almost generous towards AI: it does not simulate machines able to do nearly everything, and it lets the exposure of activities grow by at most 60 percent. Even so, the picture is clear. The economy grows. But the poorer half of the

world consumes less than it would without AI, the share of wealth going to wages shrinks by almost six points, and in the advanced economies unemployment rises for a decade without returning to where it started.

This is what happens with cautious assumptions. The case in which AI and robots really do close both refuges is one the macroeconomic model excludes out of caution. Chapter 36 tackles it, with the book's forecast occupation by occupation, demand included: by 2046, for office clerks, about six jobs in ten fewer; for software developers, four in ten; for doctors and nurses, where demand for care grows, fewer than one in ten. Chapter 37 carries the same forecast from work to social tension, country by country.

The book is meant also for readers who have not studied economics. Each concept starts from the question it serves to answer and, when it helps, from an example with numbers. Tables, charts and formulas then lead into the technical analysis, and the more complex relationships are explained in the appendix, with the symbols and the steps.

Three rules apply to every page that follows. Every real figure has its source. The model's assumptions are listed once, at the end of chapter 6, and are not repeated on every page. The code is public: anyone can download it and redo the sums. The model has not been peer reviewed, and the open code exists precisely so that anyone can carry out that check.

One last thing, which should not be hidden. This book was also prepared with the help of artificial intelligence tools (Claude, ChatGPT and Grok) for parts of the text and the code. They are products of companies that sell AI and have every interest in telling a good story about it. That is one more reason not to trust the words and to check the numbers. The choices, the conclusions and the responsibility for what is written have not been delegated to any machine.

The title says that nobody can tell you for certain what AI will do to your job. This book tells you what is most likely, and why. Not knowing everything is no reason to do nothing. Those who wait for certainty arrive when the damage is already done.

Let us start from a question that seems trivial and is not: when we say an economy is growing, what exactly is growing? And for whom?

Chapter 36

The Last Forecast

Up to here the numbers have spoken. From this page on, the forecast speaks.

It is a distinction that must be kept clear, because an honest book does not mix the two. The model showed what happens in a cautious scenario: a powerful but not omnipotent AI, exposure growing by at most 60 percent, no robot able to do almost everything. Even so, the economy grows, the poorer half loses, the door for young people narrows, unemployment rises for a decade and does not return to its starting point.

This chapter goes further. It says what to expect if today's trends continue, and it says so occupation by occupation too, with a table built on published data and rules listed only once. Those who wait for certainty arrive late.

The Forecast

Between 2026 and 2036 artificial intelligence will reduce the demand for human labor in an important part of the cognitive activities that can be standardized. In many areas it will not just be employment growing more slowly: there will be fewer jobs, in absolute terms. New jobs and increased demand will offset part of the losses. They will not reabsorb them all, and not within a time that a life can wait.

In the most exposed economies the consequence will be a long transition: harder entry, wages under pressure in many activities, value ever more concentrated in a few hands.

This forecast assumes three things: that the capabilities of the systems continue to improve, that adoption spreads, that institutions do not change fast enough to compensate. It also assumes a basic, declared choice: that incomplete reabsorption is the scenario to prepare for. Assuming that the market will rebuild on its own

an equivalent job for every job lost would be, today, a bet without foundation.

Much administrative, document-based and digital work will need fewer people. The most vulnerable activities are those in which the result can be produced and checked with information that is already digital: paperwork, standard customer support, documents, ordinary translations, repetitive content, some analyses, some phases of software development.

And AI does not have to be able to do an entire job to reduce staff. Take any office with ten people preparing paperwork and answering requests. If automation allows seven people to handle the same work, the job continues to exist. And three positions disappear. If volume grows enough, those positions can remain. The real question is not whether at least one human task remains. It is how much work grows after each person has become more productive.

The contraction will begin silently, with the jobs that are not opened. A retirement not replaced, a contract not renewed, a recruitment canceled. No mass layoffs, no headlines. That is why first entry of young people is the signal to watch before all others. An economy can look stable to those who already have a job and be ever more closed to those looking for one.

There is one thing this book does not do: it does not say how many jobs will disappear in the world. The total balance also depends on population, growth, services and public choices, and no model today can calculate it credibly. Whoever gives that number is guessing. The forecast gives the direction, the mechanism and the share of work each occupation loses, not a global figure.

The signals are already there. In the ADP payroll data collected by Brynjolfsson, Chandar and Chen, updated to August 2026, young people aged 22 to 25 employed in occupations exposed to AI in the United States are 19 percent fewer than they would have

been following the trend of their peers in less exposed jobs. Weighting the years as in chapter 3, they lose 4.2 percent a year against 0.3 for their less exposed peers; in the last year, 4.4 against 2. And the decline is moving up the age range: between 26 and 30, the most exposed occupations lose 3.1 percent in the last year, while the others stay flat. The difference arises mainly from fewer hires: the authors do not yet find widespread layoffs. [36.1]

Massenkoff and McCrory, in March 2026, distinguished what AI could do from what it actually does, also using Claude usage data. They do not find a systematic increase in unemployment in the most exposed occupations, but they find signs of a slowdown in the entry of young people. And they show that real use still covers only part of what is technically possible. It is research produced by a company in the sector, and must be read knowing that. [36.2]

The ILO estimates in 2025 that about a quarter of world employment is to some degree exposed to generative AI, and considers it more likely that jobs will be transformed rather than disappear. [36.3] But a transformed job can require fewer people. That an occupation remains on the list of jobs does not mean it keeps the same number of employed, the same entry route, the same pay.

And capabilities are growing while adoption advances. METR, in its Time Horizon 1.1 update, measures the length of software and research tasks that AI agents can complete with 50 percent success: since 2023 it has doubled about every 131 days. It concerns bounded tasks, but it says that reasoning as if today's machines were tomorrow's is a very optimistic assumption. [36.4]

Together, these data justify forecasting growing pressure on exposed jobs. The further step, that the gap between what AI can do and what it already does will be closed, and that new jobs will not be enough, is the responsibility this chapter takes on.

Why the Tractor Comparison Is Not Enough

The tractor is always cited. It took millions of people off the fields, and those people found work in factories. Bustos and co-authors documented this shift in Brazil: when agriculture became more productive, workers moved towards manufacturing, especially towards low-research-intensity industries, with largely unskilled workers. [36.5] It is a case of movement between sectors. It does not prove that every technology creates equivalent jobs.

And it worked because there was somewhere to go. Those who left the fields found the factory. Those who left the factory found the office. Brain work was for two centuries the refuge: the part that machines could not do.

AI enters precisely the refuge. Those who lose an office job and look for another job in services may find the same automation there. The boundary between the activities replaced and those that should absorb workers moves while people try to cross it. A course that today prepares for a task may find itself, at the end, facing a demand that no longer exists.

And AI does not need a new machine in every workplace. Software is distributed through the network to millions of firms at once, small ones too. The tractor had to be bought field by field. AI comes by subscription.

Software development is the closest case. This book forecasts that within about ten years writing code will stop being a job in its own right: AI tools will do it, and in its place will remain a figure closer to an architect, who decides what to build, breaks the problem down, guides the tools and checks the result. That figure will not return to today's numbers. If one person with agents does the work that today requires many programmers, getting back to the same employment would take far more software, and nobody has shown that demand can grow that much. The first signs are al-

ready there: in the last year, among software developers in the ADP sample, those aged 22 to 34 fell by 4 to 5 percent, while those aged 41 to 49 grew by 2.6; with the weights of chapter 3, 22- to 25-year-olds lose 2.7 percent a year and 41- to 49-year-olds grow by 5.1. Firms keep those who can design and take on fewer of those who write code.

The calculation is the one in Table 65, further on. AI touches 84 percent of a developer's tasks, according to the expert judgment collected by Eloundou and co-authors. Of the exposed tasks, 85 percent are substitutable, and 85 percent of these are automated by 2046: about 61 percent of the tasks pass to machines. The new roles inside the occupation give back part of them, and demand for software, which the US Bureau of Labor Statistics sees growing by 10 percent between 2025 and 2035, another part: jobs fall by 37 percent in 2036 and by 41 percent in 2046. And a problem opens that the market does not solve on its own: tomorrow's architects are today's programmers. If the first rung disappears, where will they come from?

It would have to be revised if demand for software grew enough to reabsorb developers, if firms that really use agents went back to hiring young people, or if agents remained unreliable on complex systems throughout the decade. Diffusion matters too: in 2025 in Europe, 17 percent of small firms used AI against 55 percent of large ones, and old systems, regulated sectors and public offices will keep hand-written code alive longer.

Occupation by Occupation

Manual work remains. For many it is the last safety net: if the office empties, there will always be the plumber, the warehouse worker, the nurse, the bricklayer.

This book forecasts that this refuge too will shrink. The main limit of robots was never the mechanical arm: it was the brain. A robot could repeat a movement in an orderly factory, not deal with a building site, a home, a warehouse where every day is different. Artificial intelligence is exactly what was missing. When a machine that can see, understand and plan is put inside a body that can move, the physical work that seemed protected begins to be protected no longer.

Today's numbers say where we start from. According to the International Federation of Robotics, in 2024 there were 4.66 million industrial robots in operation in the world, 9 percent more than the previous year, almost all inside orderly factories, repeating precise movements. Service robots and humanoids are still at the beginning, expensive and not widespread. But the history of technologies teaches that the initial phase, expensive and clumsy, is also the one in which it is easiest to underestimate them. Korinek and Suh, in their scenarios, show what would happen if automation came to cover almost all cognitive and physical activities: wages could rise as long as something remains that only people can do, and collapse when that something runs out. This book's model excludes that scenario out of caution. This chapter does not take it as certain, but refuses to take it as impossible.

It will not all happen at once or everywhere. Costs, reliability, safety and regulation will slow things down. Many care and relational jobs will hold out longer. But the direction is clear. If AI closes the refuge of brain work and AI with robots begins to close that of manual work, the question that has accompanied every technological revolution, where will people go, is left without an automatic answer.

Table 65 turns the forecast into numbers for nineteen occupations, in the advanced economies: how many jobs there will be in 2036 and 2046 compared with 2026, with AI, robots and the de-

mand for each occupation. There are five rules, and they apply to every occupation.

The first is exposure. For AI it is the share of an occupation's tasks whose time a GPT-type system, with its tools, can at least halve, according to the judgment of human experts collected by Eloundou, Manning, Mishkin and Rock in Science in 2024. For routine office jobs the higher of this and the probability of automation estimated by Frey and Osborne in 2013 counts, which for the office clerk is 0.96. For robots the Frey and Osborne probability for manual jobs counts.

The second is the type of work, which decides how much of the exposed tasks is substitutable and how much of that is actually automated by 2046: 85 and 85 percent in routine office and content work, 70 and 70 in design with AI tools, 55 and 47.5 where responsibility and human contact count, 55 and 70 in manual work, for the part done by AI. For robots the Frey and Osborne probability is already the automatable share of the occupation, and 70 percent of it is automated by 2046. The distinction follows the International Monetary Fund's distinction between exposure and complementarity.

The third is time. Adoption follows the book's S-curve, with central year 2033. For call center agents and office clerks the central year is calculated so that the first year reproduces the decline of customer service in the ADP data, weighted by year as in chapter 3 and measured against peers in less exposed jobs: minus 1.9 percent a year. For software developers the decline concerns only those under thirty, while above thirty employment grows: the central year stays 2033. Robots arrive five years after AI.

The fourth is the new roles inside the same occupation: for every ten tasks lost, one and a half come back, three years later. In the emerging economies everything arrives three years later, in the low-income countries six and a half years later.

The fifth is demand. The work machines take over is not the same as jobs lost when an occupation is needed more and more. Each occupation keeps the growth projected by the US Bureau of Labor Statistics between 2025 and 2035, in the projections published on 21 September 2026, at the same pace to 2046. The Bureau attributes to AI only the decline of office and administrative jobs: for the office clerk and the call center agent demand is held flat, so that automation is not counted twice.

Table 65 – Jobs by occupation in the advanced economies in 2036 and 2046, compared with 2026, with AI, robots and demand for the occupation. AI: Eloundou, Manning, Mishkin and Rock (2024) and Frey and Osborne (2013). Robots: Frey and Osborne (2013). Demand: change 2025–2035 from the Bureau of Labor Statistics, flat for office jobs. Data: aimodel, outputs/occupations.json, the same as the simulator.

Occupation	AI	Robots	Demand	2036	2046
Retail clerk	45%	92%	−0.3%	−30%	−68%
Factory worker	18%	97%	+1.1%	−23%	−61%
Office clerk	95%	–	flat	−50%	−58%
Journalist	83%	–	−5.9%	−45%	−57%
Accountant	94%	–	+5.0%	−45%	−53%
Call center agent	86%	–	flat	−45%	−53%
Driver	31%	79%	+3.8%	−21%	−53%
Translator	88%	–	+2.0%	−43%	−52%
Graphic designer	82%	–	−1.7%	−42%	−52%
Warehouse worker	12%	85%	+1.8%	−18%	−52%
Cook	16%	96%	+12.1%	−14%	−51%
Construction worker	5%	88%	+7.3%	−13%	−46%
Software developer	84%	–	+10.2%	−37%	−41%
Solution architect	82%	–	+7.9%	−23%	−23%
Teacher	52%	–	−0.2%	−10%	−12%
Lawyer	80%	–	+4.7%	−11%	−10%
Electrician / plumber	18%	25%	+8.3%	−2%	−7%
Doctor	54%	–	+3.3%	−7%	−6%
Nurse	57%	–	+5.6%	−5%	−3%

These are jobs in that occupation, not unemployment: people can move elsewhere, if they find somewhere to go. At the top are the jobs that robots reach and office work: the retail clerk loses 30 percent of the jobs in 2036 and 68 in 2046, the factory worker 23 and 61, the office clerk 50 and 58, the journalist 45 and 57. Where demand grows, the account changes. The nurse hands 13 percent of the work to machines, mostly documentation and paperwork, but the care needed increases, and in 2046 jobs are only 3 percent fewer: the time freed goes back to patients. The cook loses half of the jobs and the construction worker almost half; the electrician 7 percent. The doctor loses 6 percent, the teacher 12. The simulator published with the book uses the same data and the same rules, and gives the same numbers.

And the work needed to build all this? Semiconductors, data centers, networks, energy and maintenance require people. But this book's forecast is that this work will be much less than what it replaces: fewer people, with different skills, in different places, for different periods. A robot factory does not employ as many workers as the robots it produces replace. If it did, nobody would buy the robots.

The argument for recovery has a logic. Lower costs lower prices, lower prices broaden demand, demand creates new products and new jobs. Those who become more productive receive more orders and hire. These channels exist, and that is why an hour saved is not automatically a job lost.

But for the recovery to be complete, four things are needed together: enough jobs, soon enough, with the right skills, in the right places. That new activities arise proves none of the four. Assuming all of them as the natural outcome of such a broad transformation is an act of faith, not a forecast.

Jobs supervising AI also have a limit. If one person can check the work of ten machines, supervision remains human, but the

number of people falls. Some supervisors will be more qualified and better paid. They will be few.

And training helps to compete for jobs, it does not multiply them. If many people are prepared for few opportunities, training decides who wins, not how many win. Chapter 31 showed it. Proposing retraining as a general answer, without measuring it, means attributing to it a power nobody has yet demonstrated.

Young People and the Experience No Longer Gained

The most worrying part of the forecast concerns the way people become experts. Many entry-level tasks serve at once to produce and to learn: a first analysis, a draft to correct, the most common requests, the errors to observe. If AI removes them, firms will continue to look for experienced people, and offer fewer and fewer occasions to become one. Today's gain prepares tomorrow's void.

A professional practice can produce more documents with the same experts and hire fewer trainees. A library can automate initial cataloguing and keep only those who assess the difficult cases. The expert and the beginner use the same tool, and do not receive the same advantage from it.

The book's age module, in chapter 8, shows the same mechanism in simulation. The American data show it in reality. They point to the same door.

A postponed entry postpones everything else: independence, a home, the plans that require a stable income. A return to a lower-paid job leaves intact the debts incurred before. The model does not quantify these consequences. They are no less real for that.

The pressure will go beyond those directly replaced. If those leaving office work look for work in less automated services,

competition for those jobs increases, and wages suffer. Other sectors are not a bottomless container.

Care, maintenance, education and local services have enormous needs. But a need becomes a paid job only when someone finances it, organizes it and prepares people to do it. A bank clerk does not become a nurse because nurses are needed. The distance between need and paid demand is the place where policy can change the outcome.

The most dangerous combination is visible growth accompanied by personal opportunities that are ever harder to reach. It can strain trust in education as a road to improvement, and in institutions as a pact between contribution and protection. The social risk is that many people experience progress as something that takes away their power and role, while total wealth grows.

Chapters 33–35 are the starting point. Chapter 33 brings together growth, labor share, distribution and entry. Chapter 34 shows how much the circle between work and incomes weighs. Chapter 35 compares the interventions. From there comes the basis of the forecast: more productive capacity can coexist for a long time with fewer opportunities and with a loss for part of households.

The partial recovery of unemployment remains in the accounts. But it is an incomplete recovery: unemployment does not return to zero, the loss of the poorest continues. And that unemployment falls after a peak does not mean that the same people have recovered work, income and lost years.

The difficult scenarios of chapter 34 show that the damage is amplified precisely when getting back in is hard. Preparing only for the reassuring scenario would be unwise.

And what the calculation leaves out can weigh. The model does not reconstruct the experience lost by those who enter late, nor

every social effect of lost income. These absences prevent a curve that rises again from being presented as a problem solved.

The path to 2046 has three phases. Between 2026 and 2030 the transformation will be seen mainly in hiring: jobs not opened, missed replacements, digital work teams reorganized. Some services will grow, others will need fewer people. The gap between those with experience and those trying to gain it can widen a great deal, even without a visible increase in unemployment.

Between 2030 and 2036 the shift will be from help on single tasks to the reorganization of whole sequences of work. If systems are reliable and cheap enough, firms will redesign complete document and digital procedures, and the pressure will rise on intermediate roles too, not only on entry-level ones.

Between 2036 and 2046 an incomplete adjustment is more likely than spontaneous compensation. New activities will absorb work, but lasting differences between territories and groups will remain. And in this phase AI-driven robotics will extend automation to a growing part of physical work: this is where, in Table 65, retail clerks and factory workers lose more than six jobs in ten, drivers, warehouse workers and cooks more than half. But the employment difficulty forecast does not depend on it. Even if no manual work were automated, the transition described would remain hard.

The years mark phases, not appointments. The thread that links them is one: the capacity to produce grows faster than the capacity of institutions to distribute opportunities and incomes. How it ends depends on the decisions taken along the way, not on the technology.

What Would Refute This Forecast

A forecast that cannot be refuted is worth nothing. This one can be.

It would have to be revised if, in firms that really use AI, output growth sustained employment and working hours over time, with hiring of young people at least equal to that of similar firms that do not use it.

It would have to be revised if new tasks opened learning paths and additional jobs on a scale comparable to the losses. An increase in total employment in a period of strong general growth would not be enough to prove it.

It would have to be revised if the people affected really recovered income and job quality, or if the spread of AI remained held back by costs, reliability and organization much more than forecast here. AI can be technically impressive and have a smaller effect on work than expected.

And it would have to be revised, on manual work, if AI-driven robots remained confined to a few controlled environments throughout the next decade.

If instead the transition went well thanks to effective policies, the forecast of the social outcome would change. But it would not prove that reabsorption was automatic. It would prove that choices matter.

Preparing for this forecast means treating the loss of opportunities as a central problem of growth, not as a side effect. Training addresses part of it. Shorter hours, demand for services, support during the transition and wider access to capital income address other parts. No tool, alone, rebuilds the previous balance.

In concrete terms, the forecast points to three urgencies. The first is the entrance door: if young people no longer find the tasks from which the trade was learned, someone must build other ways for them to learn it, and someone must pay for them. The second is ownership: if value moves towards those who own machines and infrastructure, it must be decided now how to broaden that ownership, before it concentrates entirely. The third is time: ser-

vices, funds and rules take years, and the peak of the transition, in the model, arrives towards the end of the 2030s.

When production requires less paid work, distribution becomes the main question. If a growing part of value goes to those who own technologies and infrastructure, access to that value will depend more and more on rights, contracts and institutions, and less and less on hours worked. A society can turn the time saved into services and free time for all. Or it can let it become exclusion from income for many. Technology makes both roads possible. It does not decide who pays.

This is the book's forecast. Artificial intelligence will significantly reduce job opportunities in exposed activities, and with robots it will also approach manual ones. Reabsorption will be slower and more incomplete than the comparisons with past revolutions promise. What awaits us is an economy able to produce more with less human work. If institutions do not change, the value freed by machines will go to those who own them. For it to go also to those who will no longer be called to work in the same forms, it has to be decided. And it has to be decided now.

Excerpt

This is a free excerpt of The Last Forecast by Enrico Lorenzo De Vito: cover, Introduction and Chapter 36, with Table 65 of the forecast by occupation.

The full book has 37 chapters and the conclusions, with the notes, the references and the appendix with all the relationships of the model.
